

307307 Part 2 – Introduction to Large Language Models

Preface

- In the previous section, we used Bow and TDIDF to convert documents and words into numerical representations.
- These representations were simple, they had no semantics for words, just on/off switches for existing and non-existing words in a document.
- In this part of the course, we want to convert words into meaningful list of numbers.
- These numbers are called <u>Word Embeddings</u>.
- We will use Neural Networks to create these Word Embeddings.

Introduction to Neural Networks

The Perceptron

Outcomes

- Fundamentals of neural networks
- Evolution from single perceptrons to MLPs
- Detailed MLP architecture (input, hidden, and output layers)
- Mathematical representations
- Various activation functions (Sigmoid, ReLU, etc.)
- Backpropagation and training methodologies
- Loss functions and optimization techniques
- Architecture design considerations
- Real-world applications
- Advantages and limitations
- Modern MLP variants and implementations

History of Neural Networks

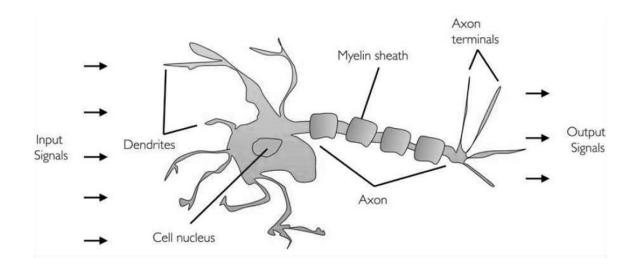

- In 1943, researchers Warren McCullock and published their first concept of simplified brain cell.
- This was called McCullock-Pitts (MCP) neuron.
- They described such a nerve cell as a simple logic gate with binary outputs.
- Multiple signals arrive at the dendrites and are then integrated into the cell body, and, if the accumulated signal exceeds a certain threshold, an output signal is generated that will be passed on by the axon.

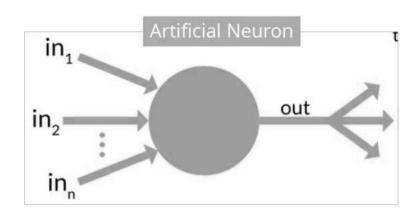

Warren Sturgis McCulloch (1898 – 1969)

Walter Harry Pitts, Jr. (1923 – 1969)

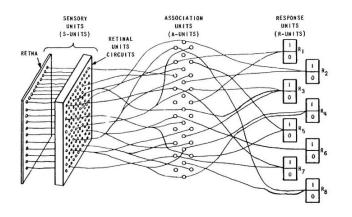

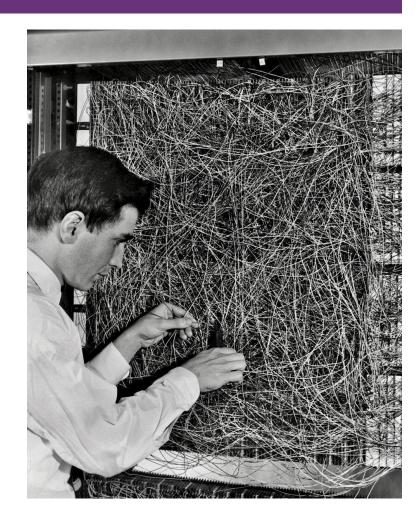

The Perceptron: Building Block of Neural Networks

- In 1953, inspired by McCullock work, Frank Rosenblatt invented the Perceptron.
- The Perceptron is the simplest form of a neural network
- Binary classifier: separates data into two categories
- Models a single neuron with multiple inputs and one output

The Perceptron

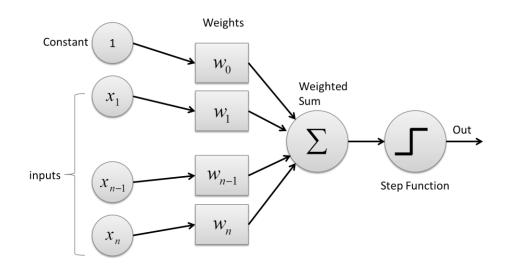

• Inputs: x₁, x₂, ..., x_n

• Weights: w₁, w₂, ..., w_n

• Bias: b

• Activation function: Step function

• Output: 1 if weighted sum > threshold, 0 otherwise

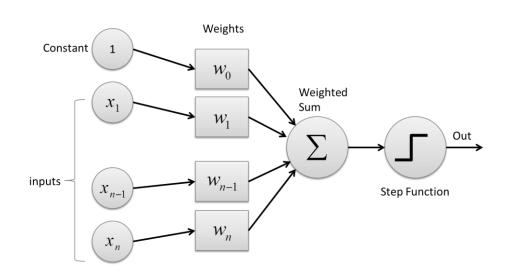

How a Perceptron Works

- 1. Multiply each input by its corresponding weight
- 2. Sum all weighted inputs
- 3. Add the bias term
- 4. Apply the activation function
- 5. Output the result

Mathematically:

•
$$z = w_1x_1 + w_2x_2 + ... + w_nx_n + b$$

output = activation(z)

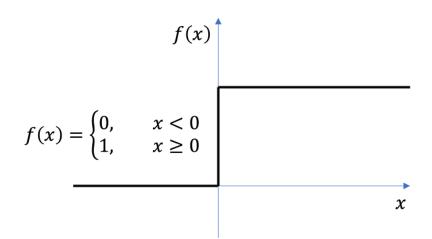

Perceptron Activation Function

- Step Function:
 - Output: 1 if $z \ge 0$, 0 if z < 0
 - Used in original perceptrons
 - Not differentiable at 0

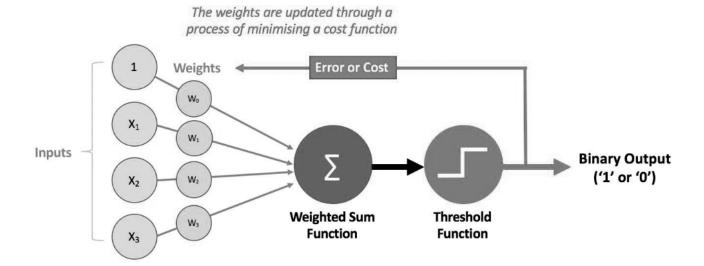

How Perceptron Learn (The Cost Function)

For each training example:

- 1. Calculate predicted output y_pred
- 2. Calculate error: error = y_true y_pred
- 3. Update weights: w_new = w_old + learning_rate * error * x
- 4. Update bias: b_new = b_old + learning_rate * error

Step-by-Step Hand Calculation for AND Gate

Let's work through the perceptron learning algorithm by hand for the AND gate:

- Training data: X = [[0,0], [0,1], [1,0], [1,1]], y = [0, 0, 0, 1]
- Learning rate (η) = 0.1
- Initial weights (randomly assigned): $w_1 = 0.3$, $w_2 = -0.1$
- Initial bias: b = 0.2

First Iteration:

Example 1: $(0,0) \rightarrow 0$

- Inputs: $x_1 = 0$, $x_2 = 0$
- Weighted sum: $z = w_1x_1 + w_2x_2 + b = 0.3(0) + (-0.1)(0) + 0.2 = 0.2$
- Activation: output = 1 (since z > 0)
- True output: y = 0
- Error: error = y output = 0 1 = -1
- Weight updates:
 - $w_1 = w_1 + \eta$ * error * $x_1 = 0.3 + 0.1$ * (-1) * 0 = 0.3
 - $w_2 = w_2 + \eta$ * error * $x_2 = -0.1 + 0.1$ * (-1) * 0 = -0.1
 - $b = b + \eta * error = 0.2 + 0.1 * (-1) = 0.1$

Step-by-Step Hand Calculation for AND Gate

Example 2: $(0,1) \rightarrow 0$

- Inputs: $x_1 = 0$, $x_2 = 1$
- Weighted sum: $z = w_1x_1 + w_2x_2 + b = 0.3(0) + (-0.1)(1) + 0.1 = 0$
- Activation: output = 1 (since z ≥ 0)
- True output: y = 0
- Error: error = y output = 0 1 = -1
- Weight updates:
 - $w_1 = w_1 + \eta$ * error * $x_1 = 0.3 + 0.1$ * (-1) * 0 = 0.3
 - $w_2 = w_2 + \eta$ * error * $x_2 = -0.1 + 0.1$ * (-1) * 1 = -0.2
 - $b = b + \eta * error = 0.1 + 0.1 * (-1) = 0$

Example 3: $(1,0) \rightarrow 0$

- Inputs: $x_1 = 1$, $x_2 = 0$
- Weighted sum: $z = w_1x_1 + w_2x_2 + b = 0.3(1) + (-0.2)(0) + 0 = 0.3$
- Activation: output = 1 (since z > 0)
- True output: y = 0
- Error: error = y output = 0 1 = -1
- Weight updates:
 - $w_1 = w_1 + \eta * error * x_1 = 0.3 + 0.1 * (-1) * 1 = 0.2$
 - $w_2 = w_2 + \eta * error * x_2 = -0.2 + 0.1 * (-1) * 0 = -0.2$
 - $b = b + \eta * error = 0 + 0.1 * (-1) = -0.1$

Step-by-Step Hand Calculation for AND Gate

Example 4: $(1,1) \rightarrow 1$

- Inputs: $x_1 = 1$, $x_2 = 1$
- Weighted sum: $z = w_1x_1 + w_2x_2 + b = 0.2(1) + (-0.2)(1) + (-0.1) = -0.1$
- Activation: output = 0 (since z < 0)
- True output: y = 1
- Error: error = y output = 1 0 = 1
- Weight updates:
 - $w_1 = w_1 + \eta$ * error * $x_1 = 0.2 + 0.1$ * 1 * 1 = 0.3
 - $w_2 = w_2 + \eta$ * error * $x_2 = -0.2 + 0.1$ * 1 * 1 = -0.1
 - $b = b + \eta * error = -0.1 + 0.1 * 1 = 0$

End of Iteration 1:

- Updated weights: $w_1 = 0.3$, $w_2 = -0.1$
- Updated bias: b = 0

Second Iteration

Example 1: $(0,0) \rightarrow 0$

- Inputs: $x_1 = 0$, $x_2 = 0$
- Weighted sum: $z = w_1x_1 + w_2x_2 + b = 0.3(0) + (-0.1)(0) + 0 = 0$
- Activation: output = 1 (since $z \ge 0$)
- True output: y = 0
- Error: error = y output = 0 1 = -1
- Weight updates:
 - $w_1 = w_1 + \eta$ * error * $x_1 = 0.3 + 0.1$ * (-1) * 0 = 0.3
 - $w_2 = w_2 + \eta$ * error * $x_2 = -0.1 + 0.1$ * (-1) * 0 = -0.1
 - $b = b + \eta * error = 0 + 0.1 * (-1) = -0.1$

Example 2: $(0,1) \rightarrow 0$

- Inputs: $x_1 = 0$, $x_2 = 1$
- Weighted sum: $z = w_1x_1 + w_2x_2 + b = 0.3(0) + (-0.1)(1) + (-0.1) = -0.2$
- Activation: output = 0 (since z < 0)
- True output: y = 0
- Error: error = y output = 0 0 = 0
- Weight updates (no change as error = 0):
 - $w_1 = 0.3$
 - $w_2 = -0.1$
 - b = -0.1
- After several iterations, the perceptron will converge to weights that correctly classify all AND gate examples.

Python Implementation Perceptron from Scratch

```
from sklearn.linear model import Perceptron
import numpy as np
   # Training data for AND gate
X = np.array([[0, 0], [0, 1], [1, 0], [1, 1]])
y = np.array([0, 0, 0, 1])
   # Initialize and train Perceptron
model = Perceptron(max iter=100, eta0=0.1, random state=42)
model.fit(X, y)
# Results
print("Weights:", model.coef )
print("Bias:", model.intercept )
print("Predictions:", model.predict(X))
Weights: [[0.2 0.2]]
Bias: [-0.2]
Predictions: [0 0 0 1]
```

The code shows a scikit-learn Perceptron implementation for the AND gate problem.

The code:

1.Imports NumPy, scikit-learn's Perceptron, and matplotlib

2. Sets up the training data for the AND gate

3.Initializes a Perceptron with 100 max iterations and a random seed of 42

4. Trains the perceptron on the AND gate data

5. Prints the learned weights, bias, and predictions

The output shows:

- Weights: [[0.2 0.2]] The perceptron learned to assign a weight of 0.2 to both inputs
- Bias: [-0.2] The bias is -0.2
- Predictions: [0 0 0 1] The perceptron correctly classified all four examples of the AND gate

With these weights and bias, the decision function is: $0.2 \times (input1) + 0.2 \times (input2) - 0.2$

For the four input combinations:

- [0,0]: $0.2\times0 + 0.2\times0 0.2 = -0.2 < 0 \rightarrow \text{output } 0$
- [0,1]: $0.2 \times 0 + 0.2 \times 1 0.2 = 0 \rightarrow \text{output } 0$
- [1,0]: $0.2 \times 1 + 0.2 \times 0 0.2 = 0 \rightarrow \text{output } 0$
- [1,1]: $0.2 \times 1 + 0.2 \times 1 0.2 = 0.2 > 0 \rightarrow \text{output } 1$

This perceptron implements the AND gate logic.

The decision boundary is the line $2x_1 + 2x_2 - 0.2 = 0$, which separates the point (1,1) from the other three points.

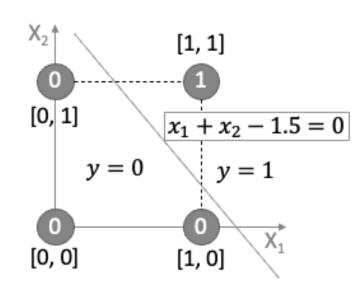

Decision Boundary

- The perceptron learns a decision boundary: $w_1x_1 + w_2x_2 + b = 0$
- Points above the line are classified as 1
- Points below the line are classified as 0
- For AND gate, only the point (1,1) should be above the line

X ₁	X ₂	У
0	0	0
0	1	0
1	0	0
1	1	1

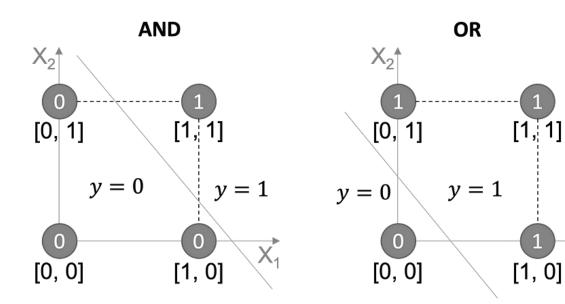

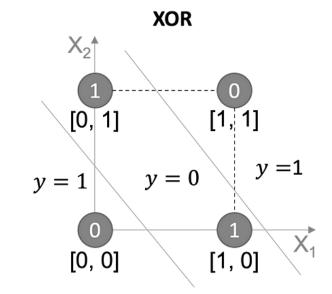

Limitations of Simple Perceptron

- Can only learn linearly separable patterns
- Cannot solve XOR problem (need multiple layers)
- No probabilistic output
- Simple update rule isn't suitable for complex problems

Introduction to Neural Networks

Multi-Layer Neural Network

The Multi-Layer Percecptron (MLP)

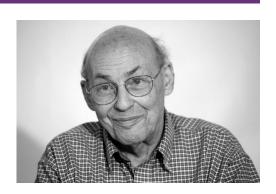

Limitations of the Perceptron

While useful for linearly separable problems, the single perceptron cannot solve complex problems like XOR classification, as demonstrated by Minsky and Papert in their 1969 book "Perceptrons."

The Multi-Layer Perceptron addresses the limitations of the single perceptron by introducing:

- Multiple layers of neurons
- Non-linear activation functions
- More sophisticated learning algorithms

Structure of an MLP

Definition: An MLP is a class of feedforward artificial neural network that consists of at least three layers of nodes: **input**, **hidden**, and **output** layers.

Key Feature: Each neuron in one layer is connected to every neuron in the next layer (fully connected).

1. Input Layer

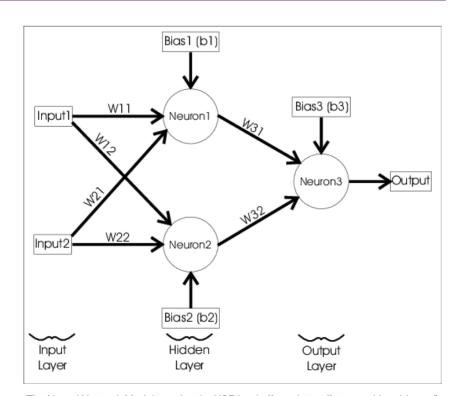

- Receives the raw input features
- One neuron per input feature
- No computation occurs here; inputs are simply passed forward

2. Hidden Layer(s)

- One or more layers between input and output
- Each neuron in a hidden layer:
- Receives inputs from all neurons in the previous layer
- Computes a weighted sum
- Applies a non-linear activation function
- Passes the result to the next layer

3. Output Layer

- Produces the final prediction or classification
- Structure depends on the task:
 - Regression: Often a single neuron with linear activation
 - Binary classification: One neuron with sigmoid activation
 - Multi-class classification: Multiple neurons (one per class) with softmax activation

The Neural Network Model to solve the XOR Logic (from: https://stopsmokingaids.me/)

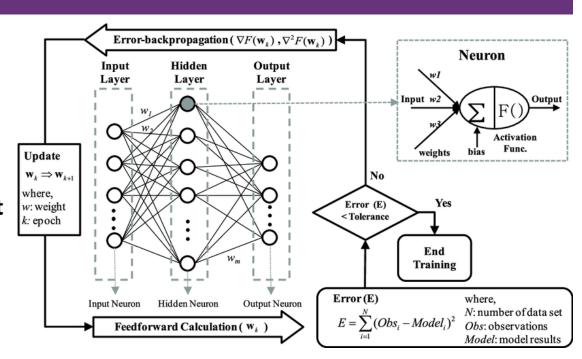

How Neural Networks Learn

Training Process:

- Feed data into the network.
- 2. Compute the output using weights.
- 3. Compare the output with the correct answer (loss calculation).
- 4. Adjust weights using **backpropagation** & **gradient descent** to improve accuracy.
- **Loss Function**: MSE for regression, Cross-Entropy for classification.
- **Optimization**: Backpropagation + Gradient Descent (or Adam).

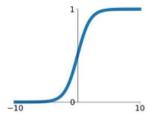

Activation Functions other than Step Function

- Neural Networks use activation functions other than the simple step function in the Perceptron.
- Activation Function helps the neural network use important information while suppressing irrelevant data points (i.e., allows local "gating" of information).

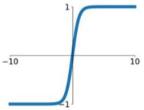

Sigmoid

$$\sigma(x) = \frac{1}{1 + e^{-x}}$$

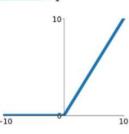

tanh

tanh(x)

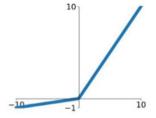

ReLU

 $\max(0, x)$

Leaky ReLU

 $\max(0.1x, x)$

Maxout

$$\max(w_1^T x + b_1, w_2^T x + b_2)$$

$$\begin{cases} x & x \ge 0 \\ \alpha(e^x - 1) & x < 0 \end{cases}$$

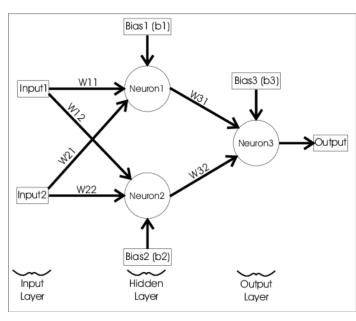

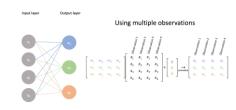

Multi-Layer Perceptron

```
from sklearn.neural_network import MLPClassifier
 import numpy as np
# XOR input and output
X = np.array([[0, 0], [0, 1], [1, 0], [1, 1]])
y = np.array([0, 1, 1, 0])
# Define MLP with 1 hidden layer of 2 neurons (minimal config for XOR)
mlp = MLPClassifier(hidden layer sizes=(2,), activation='tanh', solver='adam', learning rate init=0.01,
    max iter=10000, random state=42)
 # Train the model
mlp.fit(X, y)
# Make predictions
 predictions = mlp.predict(X)
print("Predictions:\n", predictions)
 print("\nWeights (input to hidden):\n", mlp.coefs [0])
print("\nBias hidden:\n", mlp.intercepts [0])
print("\nWeights (hidden to output):\n", mlp.coefs [1])
 print("\nBias output:\n", mlp.intercepts [1])
                                Weights (hidden to output):
Weights (input to hidden):
                                 [[-4.37775211]
[ 4.46553876]]
[-2.73418453 -3.17014048]]
Bias hidden:
                                 Bias output:
[ 1.21994174 -1.63451199]
                                 [3.61855675]
```

The Neural Network Model to solve the XOR Logic (from: https://stopsmokingaids.me/)

Introduction to Word Embeddings

How Did We Represent Words Pre-2013

- Traditional models like Bag-of-Words (BoW) or TF-IDF, treat words as independent, ignoring semantic similarity.
- One-hot encoding: Sparse, binary vectors (dimension = vocabulary size)
- Example: "king" and "queen" are as unrelated as "king" and "banana" in BoW.

Word	Dimension 1 (cat)	Dimension 2 (dog)	Dimension 3 (fish)	Dimension 4 (bird)
cat	1	0	0	0
dog	0	1	0	0
fish	0	0	1	0
bird	0	0	0	1

The Evolution of Word Representations

- Problem: How do we represent meaning mathematically?
- **Solution**: Distributional hypothesis "You shall know a word by the company it keeps" (J.R. Firth, 1957)
- J.R. Firth **did not** provide a detailed technical implementation like an algorithm or computational method. His statement was more of a **linguistic philosophy** or a **theoretical principle**, not a specific engineering method.
- And much later, it inspired the distributional hypothesis in computational linguistics, especially by scholars like Zellig Harris and later computational models (Word2Vec, etc.)

```
...government debt problems turning into banking crises as happened in 2009...

...saying that Europe needs unified banking regulation to replace the hodgepodge...

...India has just given its banking system a shot in the arm...
```

Word2Vec (Tomas Mikolov et al., 2013)

Developed by Tomas Mikolov and team at Google.

Key Innovation

• Transformed NLP by creating dense vector representations through prediction-based models

Two Architectures

- Continuous Bag of Words (CBOW):
 - Predicts target word from context words
 - Faster training, better for frequent words
- Skip-gram:
 - Predicts context words from target word
 - Better for rare words, captures more semantic information

Characteristics

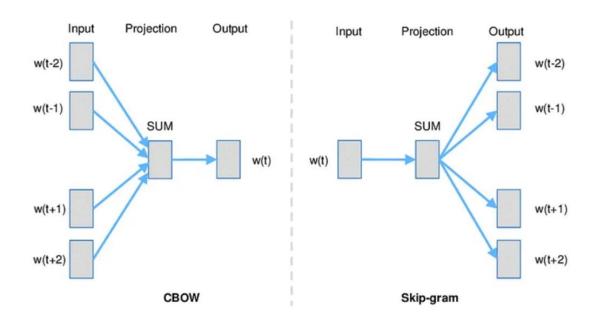

- Uses shallow neural networks and trains on local context windows.
- Typically, 100-300 dimensions (vs. vocabulary size)
- Linear relationships: king man + woman ≈ queen
- Efficient training through negative sampling
- Limitations: Fixed vectors, one vector per word regardless of context

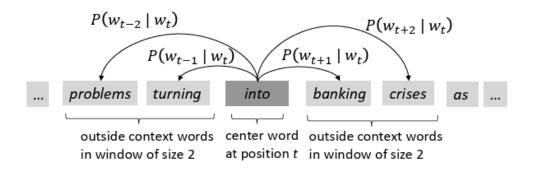

CBow and Skip-Gram Models

For each position t=1,...,T, predict context words within a window of fixed size m, given center word wt.

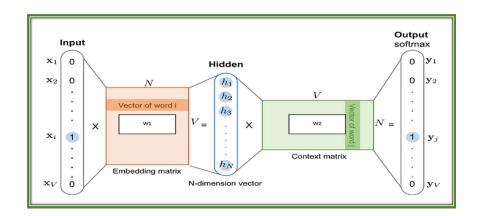

Skip-gram Architecture (Word2Vec)

This diagram illustrates how Word2Vec's **Skip-gram model** works:

- **Input**: A one-hot encoded vector for the center word (word *i*).
- Embedding Matrix: Multiplies the input vector to produce a dense embedding (N-dimensional vector) this becomes the vector representation of the input word.
- Context Matrix: The dense vector is then multiplied with another matrix to predict surrounding context words via softmax output.
- Output: A probability distribution over the vocabulary, aiming to maximize the likelihood of actual context words.
- This training process helps learn meaningful word vectors based on how words appear in context.

 $\frac{https://python.plainenglish.io/understanding-word-embeddings-tf-idf-word2vec-glove-fasttext-996a59c1a8d3}{}$

The Result of the Training Process - Similar Words -> Similar Vectors

• Visual example of how embedding changes before and after training. `sports` and `exercise` have similar embedding value post training because they are closely related

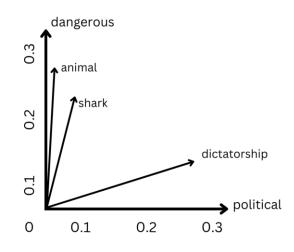

Vector Spaces and Word Embeddings

What is a Vector Space?

- A mathematical space where each word is represented as a point (or vector) in multidimensional space.
- Words are encoded as dense numerical vectors instead of one-hot or sparse representations (Word Embeddings) e.g., "king" \rightarrow [0.21, 0.72,..., 0.35]
- Word Embeddings captures semantic and syntactic relationships about/between words.
- Each dimension potentially captures semantic meaning.
- These vectors are learned from text by models like Word2Vec or GloVe.

Word	Dimension 1 (political)	Dimension 2 (dangerous)
shark	0.05	0.22
animal	0.03	0.25
dangerous	0.07	0.32
political	0.31	0.04
dictatorship	0.28	0.15

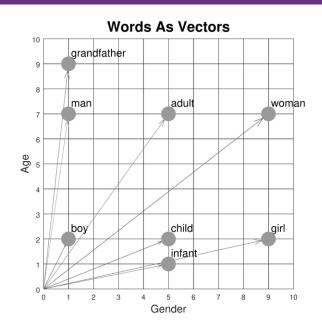

Vector Spaces and Word Embeddings

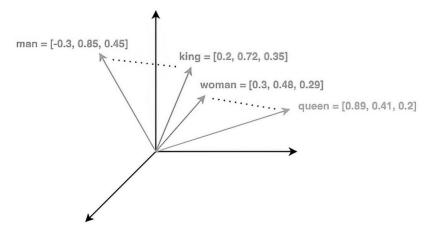

Why Use a Vector Space?

- Makes it possible to compare, visualize, and manipulate meanings of words using math.
- Enables operations like:
 - Similarity: "king" is close to "queen"
 - Analogy: "king" "man" + "woman" ≈ "queen"

Properties of Vector Space

- Semantic relationships are preserved (e.g., "shark" is closer to "dangerous" than "political").
- Similar meanings → closer vectors.
- Dissimilar meanings → vectors farther apart.

Glove (Pennington, Socher, Manning 2014)

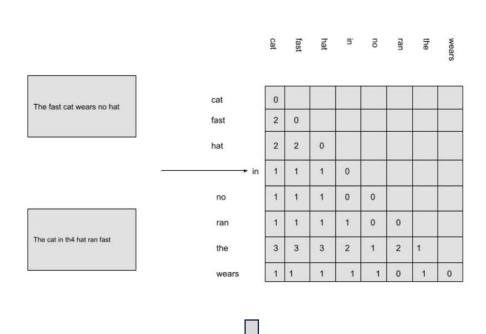

- Developed by Stanford NLP Group (Pennington, Socher, Manning)
- Key Innovation

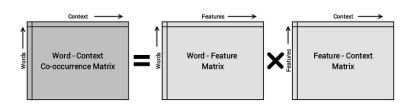

Bridges the gap between count-based methods and prediction-based methods by using global co-occurrence statistics to learn word vectors

- Approach
- Builds a word-word co-occurrence matrix over a large corpus
- Learns embeddings by factorizing the matrix using a weighted least squares objective

Characteristics

- Captures global statistical information while maintaining useful properties of local context
- Produces dense word vectors (typically 100–300 dimensions)
- Linear relationships in vector space are preserved: king man + woman
 ≈ queen
- Trained on massive corpora (Wikipedia, Common Crawl)
- Limitations: Ignores context variability—still one vector per word regardless of usage

Measuring Similarity Between Word Vectors

Why Compare Word Vectors?

- Word embeddings map words into a vector space.
- Words with similar meanings are placed close together in that space.
- To quantify this "closeness," we use vector similarity.

Cosine Similarity

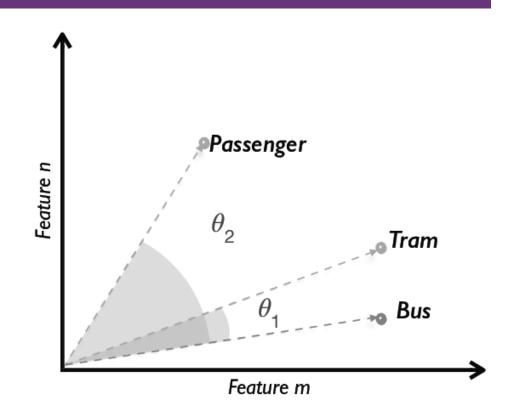

Most common metric used to compare word vectors:

$$\operatorname{cosine_similarity}(\vec{A}, \vec{B}) = \frac{\vec{A} \cdot \vec{B}}{\|\vec{A}\| \|\vec{B}\|}$$

- Measures the angle between two vectors (not their magnitude).
- Ranges from -1 to 1:
 - 1 → Same direction (very similar)
 - $0 \rightarrow Orthogonal$ (unrelated)
 - -1 → Opposite directions (very different)

Intuition

- Vectors for "king" and "queen" will have high cosine similarity.
- Vectors for "apple" and "keyboard" will have low similarity.

Experimenting with Fake Embeddings

```
import numpy as np
from sklearn.metrics.pairwise import cosine_similarity
# Fake word vectors (3D for simplicity)
word_vectors = {
    "king": np.array([0.8, 0.65, 0.1]),
    "queen": np.array([0.78, 0.66, 0.12]),
    "man": np.array([0.9, 0.1, 0.1]),
    "woman": np.array([0.88, 0.12, 0.12]),
    "apple": np.array([0.1, 0.8, 0.9]),
def similarity(w1, w2):
   return cosine_similarity([word_vectors[w1]], [word_vectors[w2]])[0][0]
print("Similarity(king, queen):", similarity("king", "queen"))
print("Similarity(man, woman):", similarity("man", "woman"))
print("Similarity(king, apple):", similarity("king", "apple"))
```

Learn Embeddings From Scratch

```
from gensim.models import Word2Vec
# Sample corpus
sentences = [['data', 'science', 'is', 'fun'],
     ['machine', 'learning', 'is', 'powerful'],
     ['data', 'and', 'learning', 'are', 'related']]
# Train the model
model = Word2Vec(sentences, vector size=50, window=2, min count=1, workers=2)
# Access the embedding for a word
print("Vector for 'data':\n", model.wv['data'])
# Find similar words
print("Words similar to 'data':", model.wv.most similar('data'))
Vector for 'data':
[-0.01723938 0.00733148 0.01037977 0.01148388 0.01493384 -0.01233535

 0.00302193 0.00358008]
Words similar to 'data': [('are', 0.16563551127910614), ('fun', 0.13940520584583282), ('learning', 0.1267007291316986), ('powerful', 0.08872982114553452), ('is', 0.011071977205574512), ('and', -0.027849990874528885),
```

Use Pre-Trained Embeddings

Gensim

- Gensim is a powerful open-source Python library designed specifically for unsupervised topic modeling and natural language processing tasks, with a strong focus on working with large corpora.
- It excels in handling word embeddings and semantic similarity, offering efficient implementations of models like Word2Vec, FastText, and Doc2Vec.
- Gensim is known for its memory-efficient, streamingbased approach, which allows it to process text data without loading everything into memory.
- This makes it especially useful for working with realworld, large-scale text data.

```
import gensim.downloader as api
from gensim.models import Word2Vec
# Load pre-trained Word2Vec model
word2vec model = api.load("word2vec-google-news-300")
# Find similar words
similar words = word2vec model.most similar('computer', topn=5)
print("Words similar to 'computer':", similar words)
# Word analogies
result = word2vec_model.most_similar(positive=['woman', 'king'],
   negative=['man'], topn=1)
print("king - man + woman =", result)
# Train your own Word2Vec model
sentences = [["cat", "say", "meow"], ["dog", "say", "woof"]]
model = Word2Vec(sentences, vector size=100, window=5, min count=1,
   workers=4)
# Get vector for a word
cat vector = model.wv['cat']
print("Vector for 'cat':", cat_vector[:5]) # Show first 5 dimensions
```

Word Embeddings Example using Spacy Library

spaCy

- spaCy is a fast and robust natural language processing library for Python that provides industrial-strength tools for text preprocessing and linguistic analysis.
- It comes with pre-trained models for multiple languages and supports features like tokenization, part-of-speech tagging, named entity recognition, dependency parsing, and sentence segmentation.
- spaCy is designed for performance and ease of use in production environments and integrates well with deep learning libraries.
- While it's not primarily focused on word embeddings, it includes pre-trained word vectors and supports similarity comparisons out of the box.

- pip install spacy
- python -m spacy download en_core_web_md

```
import spacy
nlp = spacy.load("en_core_web_md")

word1 = nlp("king")
word2 = nlp("queen")
print("Similarity:", word1.similarity(word2))
```

Applications of Word Embeddings in NLP

1. Semantic Similarity

Measure how similar two words, phrases, or documents are by comparing their vector representations. Example: Identifying that "doctor" and "physician" are closely related.

2. Text Classification

Used as input features for tasks like spam detection, sentiment analysis, and topic classification. Embeddings provide rich, dense input for machine learning models.

3. Named Entity Recognition (NER)

Help identify proper nouns and classify them into categories like person, location, or organization. Embedding-based models improve contextual understanding of named entities.

4. Machine Translation

Map words from one language to another by aligning embeddings in multilingual space. Improves translation accuracy by leveraging semantic proximity.

5. Question Answering & Chatbots

Used to understand queries and match them with appropriate answers or responses. Enable bots to interpret intent and context more accurately.

6. Information Retrieval

Enhance search engines by retrieving results based on semantic meaning, not just keyword matches. Example: Searching for "heart attack" returns documents containing "cardiac arrest."

Introduction to Deep Neural Networks

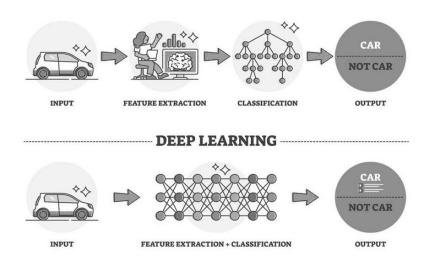

Introduction to Deep Learning

- Neural Networks have revolutionized artificial intelligence by enabling machines to learn from data in ways that mimic human neural processes.
- Deep neural networks (DNNs) are Neural Networks that are composed of multiple processing layers that can learn representations of data with multiple levels of abstraction.
- The power of deep learning comes from its ability to automatically discover intricate patterns in raw data through the learning process, without requiring human engineers to manually specify all the knowledge needed by the computer system.

input layer hidden layer 1 hidden layer 2 hidden layer 3 output layer

Deep Neural Network

Introduction to Deep Learning

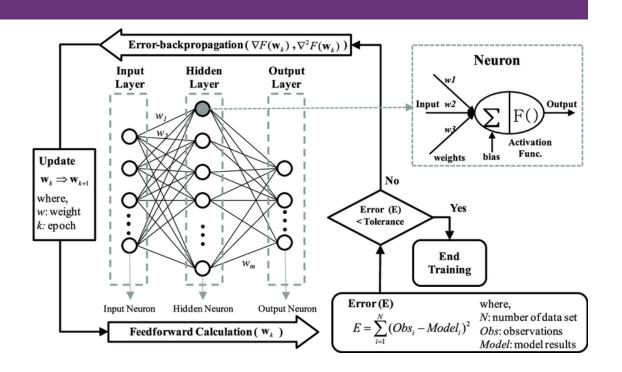

Fundamentals of Neural Networks

At their core, neural networks consist of:

- **1. Neurons**: Mathematical functions that take inputs, apply weights, add a bias, and produce an output
- **2. Layers**: Collections of neurons that process information in stages
- **3. Activation Functions**: Non-linear functions that introduce complexity into the network
- **4. Weights and Biases**: Parameters that are adjusted during training

The basic workflow involves:

- Forward propagation: Data flows through the network
- Loss calculation: The network's prediction is compared to the actual value
- Backpropagation: Errors are propagated backward to update weights
- Optimization: Weights are adjusted to minimize errors

Convolutional Neural Networks

CNNs revolutionized image processing by introducing specialized layers that mimic how the visual cortex processes information.

Key components include:

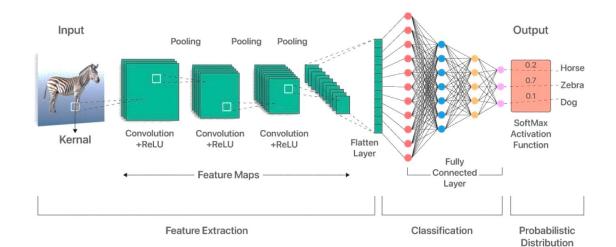

- 1. Convolutional Layers: Apply filters that scan across the input data to detect patterns
- **2. Pooling Layers**: Reduce dimensions while preserving important features
- **3. Fully Connected Layers**: Connect every neuron to every neuron in adjacent layers

Instead of each neuron connecting to every pixel in an image (which would be computationally expensive), CNNs use:

- Local connectivity: Neurons connect only to nearby pixels
- Parameter sharing: The same filter is applied across the entire image

Business applications include:

- Product image recognition
- Visual quality control in manufacturing
- Document processing
- Customer behavior analysis in retail

30	3	22	1	0

2	0	0	0	1

_			
	12.0	12.0	17.0
	10.0	17.0	19.0
	9.0	6.0	14.0

Recurrent Neural Networks (RNNs)

Unlike traditional neural networks, RNNs process sequences by maintaining a form of memory of previous inputs.

Key characteristics:

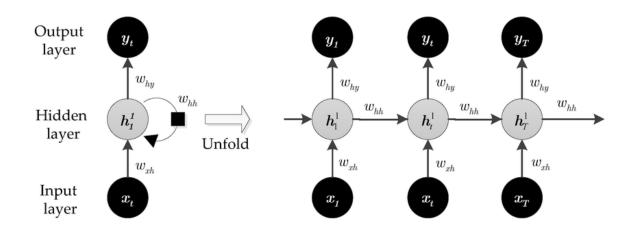

- Time-dependent processing: Output depends on both current and previous inputs
- Shared parameters: The same weights are applied at each time step
- Memory: Internal state acts as a form of short-term memory

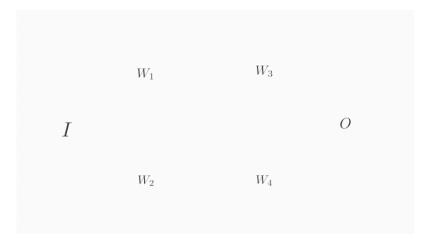

However, basic RNNs struggle with long-term dependencies due to:

- Vanishing gradient problem: The influence of early inputs fades over time
- Exploding gradient problem: Gradients grow uncontrollably during training

Business applications include:

- Language Modeling & Text Generation Predicting the next word in a sequence (e.g., autocomplete, chatbots).
- Machine Translation Translating text from one language to another.
- Speech Recognition Converting spoken language into written text.
- Stock Price Prediction Predicting future stock or financial data.
- Weather Forecasting Modeling temporal patterns in weather data.
- Patient Monitoring Analyzing sequences of medical data (e.g., ECG signals).
- Music Generation Creating sequences of musical notes.
- Fraud Detection Detecting unusual sequences in financial transactions.
- Network Intrusion Detection Monitoring patterns of activity over time.

Transformers

Transformers – Architecture and Principles

What is a Transformer?

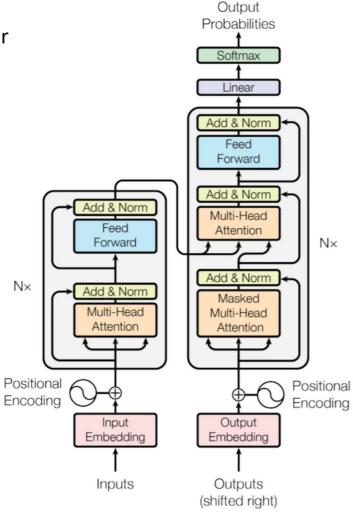

- A deep learning model based entirely on self-attention, with no recurrence or convolutions
- Introduced in the paper "Attention Is All You Need" (Vaswani et al., 2017)

Transformer Components:

- **1. Embeddings**: Convert tokens to vector representations
- 2. Positional Encoding: Adds position information
- **3. Multi-Head Attention**: Processes relationships from multiple perspectives
- 4. Feed-Forward Networks: Process each position independently
- 5. Layer Normalization: Stabilizes training
- 6. Residual Connections: Helps with gradient flow

Architecture Variations:

- Encoder-only (BERT): Good for understanding (classification, NER)
- Decoder-only (GPT): Good for generation
- Encoder-decoder (T5): Good for transformation tasks (translation, summarization)

Transformer Processing Flow

Task: Translate the English sentence:

"Your cat is a lovely cat" → "Ton chat est un chat adorable"

We'll walk through the encoder-decoder Transformer architecture used in machine translation.

Input Preparation

English sentence (source):

"The cat is sleeping"

- Tokenization: Break the sentence into tokens: ["<s>", "Your", "cat", "is", "a", "lovely", "cat", "</s>"]
- Embedding: Convert each token into a vector using a learned embedding matrix.
- Positional Encoding: Add position-based information to each token embedding to represent word order.
- Without this, the self-attention mechanism would treat the sentence as a bag of words.

Embedding	Index ID	Vocabulary
[0.03 0.12 0.98]	1134	a
[0.04 0.08 0.32]	665	in
[0.45 0.01 0.03]	398	I

[0.15 0.46 0.63]	456	called
[0.45 0.01 0.04]	298	am
d		

Encoder

The encoder processes the full input sequence in parallel through a stack of layers.

Each encoder layer includes:

Multi-head Self-Attention:

Each word learns which other words to focus on. Example: The second occurrence of "cat" may attend to the first "cat" to recognize repetition or coreference.

Add & Norm:

A residual connection followed by layer normalization.

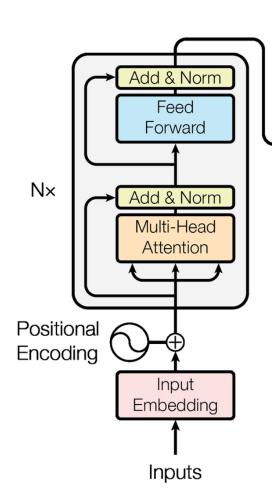

Feedforward Network:

A two-layer neural network processes each position independently.

Add & Norm:

Another residual connection and normalization.

 This stack is repeated several times (e.g., 6 layers), producing a set of contextualized vectors, one for each token.

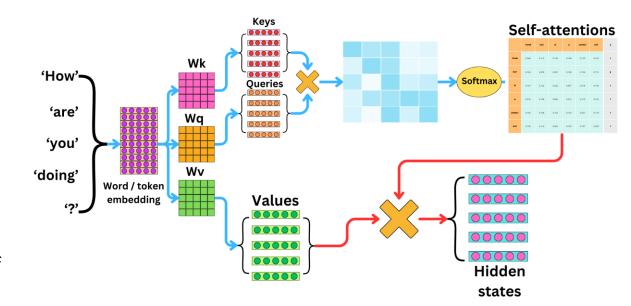

The Attention Mechanism

- **1. Create Q, K, V matrices**: Each word embedding is multiplied by three learned weight matrices (WQ, WK, WV) to create Query, Key, and Value representations:
 - $Q = X \cdot WQ$
 - K = X · WK
 - V = X · WV
- **2. Compute attention scores**: Each query vector is dotproducted with all key vectors to get raw attention scores:
 - Scores = $Q \cdot K^T$
- **3. Scale the scores**: Divide by Vdk (where dk is the dimension of the key vectors) to prevent the values from getting too large:
 - Scaled scores = (Q · K^T) / Vdk
- **4. Apply softmax**: Convert the scaled scores to probabilities:
 - Attention weights = softmax(Scaled scores)
- 5. Compute weighted values: Multiply the attention weights by the value vectors:
 - Output = Attention weights · V

So the formula is: Attention(Q,K,V) = softmax((Q·K^T)/ \sqrt{dk}) · V

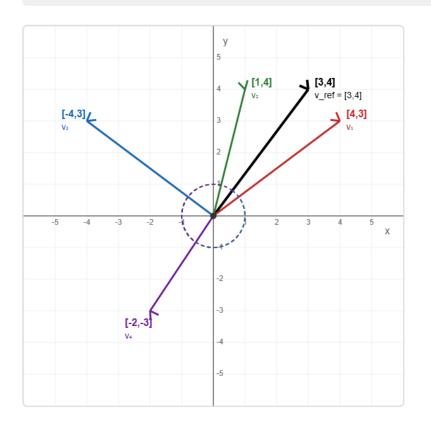

Vector Dot Product as Similarity Measure

1. Very Similar (High Positive)

Red Vector $v_1 = [4, 3]$

 $v_1 \cdot v_ref = (4 \times 3) + (3 \times 4) = 24$

Almost same direction as reference

2. Similar (Positive)

Green Vector $v_2 = [1, 4]$

 $v_2 \cdot v_ref = (1 \times 3) + (4 \times 4) = 19$

Generally same direction

3. Neutral (Zero)

Blue Vector $v_3 = [-4, 3]$

 $v_3 \cdot v_ref = (-4 \times 3) + (3 \times 4) = 0$

Perpendicular (90° angle)

4. Dissimilar (Negative)

Purple Vector $v_4 = [-2, -3]$

$$v_4 \cdot v_ref = (-2 \times 3) + (-3 \times 4) = -18$$

Opposite direction

Key Innovation: Self-Attention Mechanism

- Self-attention allows each word to compute its embedding by gathering information from all other words in the sequence.
- The "attention weights" determine how much each word should focus on other words.
- Words that are semantically related tend to have higher attention scores between them.
- This mechanism helps capture long-range dependencies and relationships regardless of word distance.
- Multiple attention heads in parallel (Multi-head Attention) allow the model to focus on different aspects of relationships.

	YOUR	CAT	ıs	٨	LOVELY	CAT	Σ
YOUR	0.268	0.119	0.134	0.148	0.179	0.152	,
CAT	0.124	0.278	0.201	0.128	0.154	0.115	*
is	0.147	0.132	0.262	0.097	0.218	0.145	1
A	0.210	0.128	0.206	0.212	0.119	0.125	1
LOVELY	0.146	0.158	0.152	0.143	0.227	0.174	1
CAT	0.195	0.114	0.203	0.103	0.157	0.229	1

Multiple Attention Heads

 Multiple attention heads in parallel (Multi-head Attention) allow the model to focus on different aspects of relationships.

Decoder Input Preparation

The Transformer decoder generates output sequences by attending to two sources:

- Previously generated tokens via masked self-attention
- The encoder's output, which provides context from the input sequence.

This enables fluent and contextually accurate generation.

Example – Target Sentence (French): "Ton chat est un chat adorable"

Training Phase:

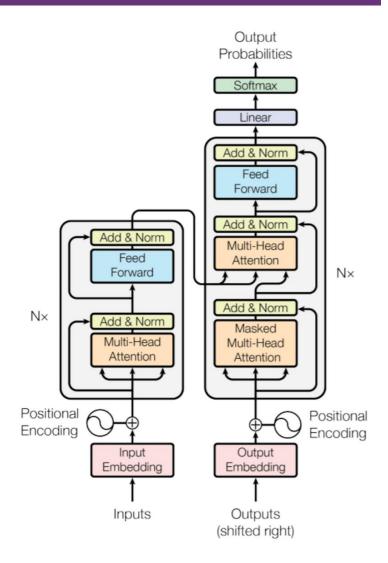

- The decoder begins with a special start-of-sequence token <s>
- At each time step, it receives the actual previous target words.
- Example: Step 1: <s>, Step 2: <s> Ton, Step 3: <s> Ton chat, etc.

Inference Phase:

- Starts with <s> and generates one word at a time.
- Each new word is used as input for the next step.
- Example: $\langle s \rangle \rightarrow Ton \rightarrow chat \rightarrow est \rightarrow ...$

Summary:

By combining attention to past outputs and the encoded input, the decoder generates coherent, context-aware text—essential for tasks like translation and summarization.

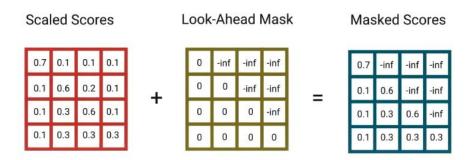

Decoder

Each decoder layer includes:

1. Masked Multi-head Self-Attention:

Looks at the previously generated French words. Future words are masked to prevent cheating.

2. Encoder-Decoder Attention:

Each decoder token can attend to all encoder outputs.

Example: The decoder token "chat" may attend to the English "cat" to align the translation.

3. Feedforward Network:

Processes each token vector separately.

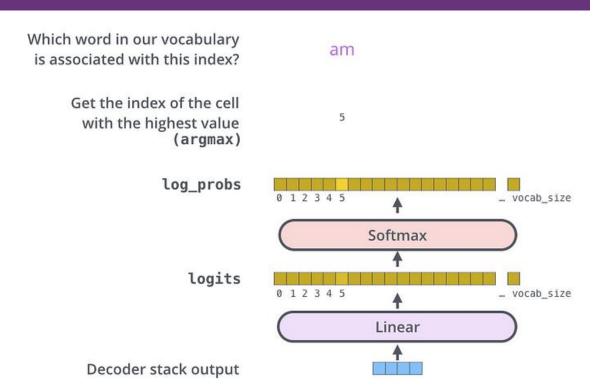

• Each sub-layer includes residual connections and layer normalization.

Output Generation

- The decoder outputs a vector at each time step.
- A linear layer followed by softmax turns this vector into a probability distribution over the French vocabulary.
- The model selects the most probable next word ("Ton", then "chat", then "est", etc.).
- This continues until an end-of-sentence token </s> is generated or a length limit is reached.

Contextual Word Embeddings

Contextual Word Embeddings (BERT and GPT)

Key Innovation

Unlike static embeddings (Word2Vec, GloVe), contextual models generate **different vectors for the same word** depending on its context.

Approach

Uses deep, pre-trained neural networks (often transformer-based)
Embeddings are derived from entire sentences, capturing syntax and semantics dynamically

Examples

- BERT (2018): Transformer-based neural networks trained with masked language modeling and next sentence prediction
- GPT (2018): Transformer-based unidirectional language model focused on generation.

Characteristics

- Embeddings are context-sensitive (e.g., "bank" in "river bank" vs. "savings bank")
- Each word is embedded based on its role in the sentence.
- Embeddings vary for the same word depending on its position and meaning.
- Significantly improve performance on downstream NLP tasks.

BERT – Overview and Architecture

What is BERT?

- A pre-trained language model based on the Transformer encoder
- Developed by Google in 2018
- Reads text bidirectionally, enabling deep contextual understanding

Key Ideas

- Uses only the **encoder** stack of the Transformer
- Pre-trained on large text corpora, then fine-tuned on specific tasks

Pretraining Objectives

- Masked Language Modeling (MLM): Predict randomly masked words in a sentence
- Next Sentence Prediction (NSP): Predict if one sentence follows another

Applications

- Sentiment Analysis
- Question Answering
- Named Entity Recognition
- Text Classification
- Semantic Search

GPT – Overview and Architecture

What is GPT?

- A family of **Transformer-based language models** developed by OpenAI
- Uses only the **decoder stack** of the original Transformer architecture
- Trained with causal (autoregressive) language modeling to predict the next token

Training Objective

Predict the next token in a sequence

GPT Variants

- **GPT-1**: Introduced the pretrain-then-finetune paradigm
- GPT-2: Scaled up model size, trained on web-scale data
- GPT-3: 175B parameters, enabled in-context learning
- **GPT-4**: Multimodal, stronger reasoning and generalization

Applications

- Text generation (e.g., chat, storytelling, code)
- Summarization
- Translation
- Question answering
- Semantic search and reasoning tasks

BERT vs. GPT

- BERT: Bidirectional, great for understanding
- GPT: Autoregressive, great for **generation**

More About BERT

What is BERT?

- Bidirectional Encoder Representations from Transformers
- Developed by Google AI Language in 2018
- Pre-trained language model that revolutionized NLP
- Based on Transformer architecture (Attention mechanism)

Key Advatages

- Contextual embeddings: Word meanings change based on context
- Captures long-range dependencies
- Pre-trained on massive datasets → Transfer learning
- State-of-the-art performance on 11 NLP tasks when released

Architecture Overview

```
Input: [CLS] The cat sat on the mat [SEP]

↓

Token Embeddings

Position Embeddings

Segment Embeddings

↓

Transformer Encoder (12 or 24 layers)

↓

Contextual Representations
```

Key Components

- · [CLS]: Classification token (sentence-level tasks)
- [SEP]: Separator token (between sentences)
- · Multi-head attention: Allows model to focus on different positions
- · Feed-forward networks: Process attention outputs

BERT Pre-training

Two Pre-training Tasks

- 1. Masked Language Model (MLM)
- Randomly mask 15% of tokens
- Predict masked tokens using context
- Example: "The [MASK] is very cute" → "cat"
- 2. Next Sentence Prediction (NSP)
- Given two sentences, predict if B follows A
- Helps understand sentence relationships
- Example:
 - A: "It is raining heavily."
 - B: "I need an umbrella." → True

BERT Variants

Common BERT Models

Model	Parameters	Layers	Hidden Size	Attention Heads
BERT-Base	110M	12	768	12
BERT-Large	340M	24	1024	16
DistilBERT	66M	6	768	12
RoBERTa	355M	24	1024	16
ALBERT	12M-235M	12-24	768-4096	12-64

Specialized Variants

• **BioBERT**: Biomedical text

• **SciBERT**: Scientific text

• **FinBERT**: Financial text

• Clinical BERT: Clinical notes

Brief Introduction to Hugging Face 🥰

The Problem They Solved **Before Hugging Face (2018)**

- Models locked in research papers
- Complex implementations
- Different APIs for each model
- Difficult to compare/use models
- Limited accessibility

After Hugging Face

- Unified API for all models
- Easy model sharing
- Standardized interfaces
- Community-driven development
- Democratized Al access

2016: Founded as a Chatbot Company

- Started with conversational Al
- Built tools for developers
- Recognized broader need

2018: The Pivot

- Released transformers library
- Open-sourced BERT implementation
- Explosive community growth

Today: The GitHub of Al

- 350,000+ models
- 50,000+ datasets
- Millions of users
- Industry standard

The Hugging Face Ecosystem

Core Components

1. Transformers Library

```
from transformers import pipeline
# One line to use any model
classifier = pipeline("sentiment-analysis")
result = classifier("I love Hugging Face!")
```

2. Model Hub

- Centralized model repository
- Version control for models
- Model cards (documentation)
- Direct integration with code

3. Dataset Library

```
from datasets import load_dataset

dataset = load_dataset("imdb")

# Automatic downloading, caching, processing
```

4. Tokenizers

- Fast tokenization (Rust-based)
- Supports all tokenization schemes
- Handles special tokens
- Production-ready speed

5. Spaces

- Host ML demos for free
- Gradio/Streamlit integration
- Share with one click
- GPU support available

Why This Matters

Impact on AI Development

- 1. Accessibility
- PhD not required √
- Free models and tools √
- Great documentation √
- Active community √

2. Reproducibility

- Standardized implementations
- Version control
- Model cards with metrics
- Easy sharing

3. Innovation Speed

- Build on others' work
- Rapid prototyping
- Easy experimentation
- Quick deployment

4. Democratization

- Small teams can compete
- Global collaboration
- Open science
- Reduced barriers

Model Hub Deep Dive

Understanding Model Cards

Every model on Hugging Face has:

- Model Card: Documentation about the model
- **Files**: Model weights, config, tokenizer
- Metrics: Performance benchmarks
- **License**: Usage restrictions
- **Tags**: Task type, language, framework

organization/model-name

Examples:

- bert-base-uncased (by Hugging Face)
- google/flan-t5-base (by Google)
- microsoft/DialoGPT-medium (by Microsoft)
- openai/whisper-large (by OpenAI)

From Concept to Code - The Pipeline Abstraction

- Traditional Approach
- 1. Load tokenizer
- 2. Preprocess text
- 3. Load model
- 4. Run inference
- 5. Post-process results
- ... 50+ lines of code

Hugging face Approach

```
from transformers import pipeline
classifier = pipeline("task-name")
result = classifier("your text")
# 2 lines!
```

Under the Hood

- 1. Automatic model selection
- 2. Tokenization handled
- 3. Inference optimization
- 4. Result formatting
- 5. Device management

Other Hugging face Piplines

The Hugging Face transformers library supports a wide range of **pipelines**, each designed for a specific **natural language processing (NLP)** or **vision** task — so you can use powerful models without deep setup.

Pipeline Name	Task Description
"sentiment-analysis"	Classify sentiment (positive/negative)
"text-classification"	General text classification (multi-label or multi-class)
"zero-shot-classification"	Classify into labels without training on them
"text-generation"	Generate text (e.g., GPT models)
"text2text-generation"	Text-to-text tasks (e.g., summarization, translation)
"translation"	Translate between languages
"summarization"	Generate a summary of input text
"question-answering"	Extract answer from context
"fill-mask"	Predict missing word in a sentence (BERT-style)
"ner" (Named Entity Recognition)	Extract entities (like names, places, etc.)
"conversational"	Chatbot-style conversation
"sentence-similarity"	Measure similarity between two sentences
"token-classification"	Classify each token (used for NER, POS tagging, etc.)
"feature-extraction"	Extract embeddings/features from a model
"table-question-answering"	QA over structured data (tables)

➤ Sentiment Analysis

➤ Summarization

python & Copy & Edit

pipeline("summarization")("Long article text goes here...")

➤ Translation

➤ Question Answering

python

Q Copy ** Edit

qa = pipeline("question-answering")

qa({
 "question": "Where do pandas live?",
 "context": "Pandas are native to China and prefer bamboo forests."
})

To list all available pipelines in code:

Example: Print out BERT Embeddings

```
from transformers import BertTokenizer, BertModel
import torch
# Load pretrained BERT
tokenizer = BertTokenizer.from pretrained('bert-base-uncased')
model = BertModel.from pretrained('bert-base-uncased')
# Sentence
sentence = "He went to the bank to deposit money."
# Tokenize
inputs = tokenizer(sentence, return_tensors='pt')
# Get outputs
with torch.no grad(): # No training, just inference
   outputs = model(**inputs)
# Get the hidden states (embeddings)
embeddings = outputs.last_hidden_state # Shape: (batch_size, sequence_length,
# (hidden_size)
print(embeddings.shape) # Example output: torch.Size([1, 11, 768])
```

Example: Question Answering using BERT

QA Task Overview

- Input: Context paragraph + Question
- Output: Answer span from the context
- BERT identifies start and end positions of answer

QA Pipeline Components

- 1. Tokenization: Convert text to tokens
- 2. Encoding: Create input embeddings
- **3. Model Inference**: Get start/end logits
- **4. Post-processing**: Extract answer text

```
# Import required libraries
from transformers import AutoTokenizer, AutoModelForQuestionAnswering
from transformers import pipeline
import torch
# Using pipeline (High-level API)
qa pipeline = pipeline( "question-answering",
model="bert-large-uncased-whole-word-masking-finetuned-squad",
tokenizer="bert-large-uncased-whole-word-masking-finetuned-squad" )
# Example usage
context = """ BERT is a method of pre-training language representations,
meaning that it trains a general-purpose language understanding
model on a large text corpus (like Wikipedia),
and then uses that model for downstream NLP tasks like question answering. """
question = "What is BERT?"
result = qa pipeline(question=question, context=context)
print(f"Answer: {result['answer']}")
print(f"Confidence: {result['score']:.4f}")
```

Model Choice Explanation

- bert-large-uncased-whole-word-masking-finetuned-squad
 - Based on BERT-Large architecture
 - Uncased: converts text to lowercase
 - Whole word masking: improved pre-training
 - Fine-tuned on SQuAD dataset (Stanford Question Answering Dataset)

Introduction to Large Language Models

Generative Al

- Generative AI, also known as GenAI, refers to a type of artificial intelligence that uses machine learning algorithms to generate new, synthetic data, such as images, videos, music, text, and more.
- Unlike traditional AI, which focuses on analyzing and processing existing data, generative AI models create novel data samples that resemble existing data.
- Some common applications of generative AI include:
 - Text generation: Creating realistic text, such as articles, stories, or chatbot responses, for use in applications like content generation, language translation, and conversational interfaces.
 - Image and video generation: Generating realistic images, videos, or 3D models for use in various industries, such as entertainment, advertising, and architecture.
 - Music and audio generation: Generating music, sound effects, or voice synthesis for use in music production, audiobooks, or voice assistants.
 - Data augmentation: Generating new data samples to augment existing datasets, which can help improve the performance of machine learning models.
 - Art and design: Creating new artistic styles, designs, or patterns for use in various creative fields.

Introduction to LLMs

- Large Language Models (LLMs) are AI models trained on massive amounts of text data to generate human-like text, answer questions, and assist in various applications.
- Some of the most advanced LLMs today come from leading AI research labs, each with unique architectures, capabilities, and use cases.
- This lecture covers the major LLMs, their features, differences, and code examples to interact with them.

Well Known Models:

Company	Model(s)	Key Features
OpenAl	GPT-4, GPT-4-turbo, GPT-3.5	Strong reasoning, multimodal (text & image in GPT-4), API for developers
Anthropic	Claude 1, 2, 3	Focus on safety, long-context handling, efficient responses
Google	Gemini 1, Gemini 1.5	Strong in reasoning, image understanding, Google search integration
Cohere	Command R+, Command R	Enterprise-focused, retrieval-augmented generation (RAG)
Meta	LLaMA 2, LLaMA 3 (upcoming)	Open-source, efficient models for researchers
Perplexity	Perplexity AI	AI-powered search engine, real-time web browsing

What is OpenAI?

- OpenAI is an artificial intelligence research and deployment company.
- Founded in December 2015 by Elon Musk, Sam Altman, Greg Brockman, Ilya Sutskever, John Schulman, and Wojciech Zaremba.
- The organization's mission is to ensure that artificial general intelligence (AGI) benefits all of humanity.
- Initially a non-profit, it transitioned in 2019 to a "capped-profit" model through the creation of OpenAI LP to attract capital while maintaining mission alignment.

Timeline of Key Models

Model	Release Year	Parameters	Training Data	Key Capabilities	Notes
GPT	2018	~117 million	Books, websites, Wikipedia, Common Crawl	Basic text generation and completion	First Generative Pretrained Transformer; proof of concept
GPT-2	2019	1.5 billion	8 million documents from the internet	Coherent paragraphs, summaries, text generation	Withheld initially due to concerns about misuse
GPT-3	2020	175 billion	~570GB filtered text (Common Crawl + curated data)	Question answering, translation, text generation, code assist	Major leap in coherence and contextual understanding
Codex	2021	Built on GPT-3	Text + 100M+ GitHub code repositories	Code generation, code completion, natural language → code	Powers GitHub Copilot
ChatGPT	2022	GPT-3.5 fine-tuned	GPT-3.5 + Human Feedback	Conversational AI, tutoring, brainstorming, creative writing	Optimized for dialogue using RLHF
GPT-4	2023	Estimated 1+ trillion*	Diverse multimodal data (text, image, web)	Multilingual, logic reasoning, coding, image input (limited)	Parameters not publicly confirmed
GPT-4o	2024	Unknown (GPT-4 variant)	Text, images, audio	Real-time interaction with vision, voice, and text capabilities	"o" stands for "omni"; supports seamless multimodal input/output

OpenAl and Microsoft Partnership

- Microsoft is a key partner and investor in OpenAl.
- Azure cloud services are used to deploy OpenAI models.
- OpenAI tools are integrated into Microsoft products like Word, Excel, and GitHub Copilot.
- Microsoft has exclusive licenses to integrate GPT models in enterprise settings.

How OpenAl Models Work

- OpenAI's models are based on the Transformer architecture, introduced by Vaswani et al. in 2017.
- These models are trained on massive datasets containing text, code, and other data from the internet.
- The models learn to predict the next word or token in a sequence (autoregressive training).
- Some models, like ChatGPT, use Reinforcement Learning from Human Feedback (RLHF) to improve response quality.
- GPT-40 is multimodal: it can accept and generate text, images, and audio.

Core OpenAl Technologies and Products

- GPT (Generative Pretrained Transformer): Language model that generates human-like text.
- ChatGPT: All chatbot used for conversation, education, and productivity.
- DALL\u00b7E: Text-to-image model that generates pictures from textual descriptions.
- Codex: Powers AI programming assistants like GitHub Copilot.
- Whisper: Open-source automatic speech recognition system.

Ethical Considerations and Safety Measures

- OpenAI aims to make AI systems that are safe and aligned with human values.
- Safety teams work on reducing harmful outputs and biases.
- Content moderation tools are integrated in public-facing applications.
- OpenAl supports responsible use and restricts applications related to misinformation, surveillance, or violence.

OpenAl Compared to Other Al Labs

- **DeepMind (Google):** Focuses on scientific discovery and AGI through models like AlphaGo and AlphaFold.
- Anthropic: Founded by former OpenAI researchers; emphasizes alignment and safety.
- Meta AI (Facebook): Focuses on open research in large language models and computer vision.
- OpenAI uniquely balances research, product development, and commercial deployment.

Applications Across Industries

- Education: Al tutoring, essay writing support, language learning.
- Business: Report generation, customer support automation, data analysis.
- Healthcare: Administrative assistance, medical information summarization.
- Software Development: Coding help through Copilot and Codex.
- Creative Work: Art generation, script writing, music composition.

Concerns and Challenges

- Bias: Models may reflect societal biases present in training data.
- Privacy: Risk of sensitive data being used in model training or output.
- Misinformation: Ability to generate plausible but false content.
- Job Displacement: Automation of cognitive tasks may affect employment.
- OpenAI acknowledges these concerns and actively works on mitigation strategies.

Future of OpenAl

- Continued improvement in model capabilities and safety.
- Focus on user customization (e.g., custom GPTs).
- Expansion of real-time multimodal interaction (text, voice, vision).
- Engagement with policymakers and public institutions to guide ethical AI development.
- OpenAI's long-term goal is to achieve safe, beneficial artificial general intelligence (AGI).

Conclusion and Discussion Points

- OpenAl is a leader in Al research and product development.
- It has transformed industries and raised important ethical questions.
- It remains committed to making AGI safe and beneficial.
- Questions for Discussion:
 - Should access to powerful AI models be open or restricted?
 - How should governments regulate AI?
 - What are the roles of education and ethics in the age of AI?

api key = os.environ.get("GROQ API KEY")
if not api key:
    print("Please set the GROQ API KEY environment variable.")
    exit
# Initialize the Grog client
client = Groq(api key=api key)
# Define a sample prompt
prompt = "What is the capital of France?"
# Create a chat completion
completion = client.chat.completions.create(
    model="compound-beta",
    messages=[
        {"role": "user", "content": prompt},
    max tokens=2048,
    stop=None,
# Print the response
print(completion.choices[0].message.content)
```

1. Import necessary libraries:

- import os: You import Python's os module, which provides functions to interact with the
 operating system (like accessing environment variables).
- from groq import Groq: You import the Groq client, which is used to communicate with Groq's
 API to call language models.

2. Load the API key:

- api_key = os.environ.get("GROQ_API_KEY"): This attempts to read the environment variable
 named GROQ_API_KEY that should contain your API key.
- If the key is not found (if not api_key:), the script prints a message asking the user to set it and
 exits immediately (exit()).

3. Initialize the Grog client:

client = Groq(api_key=api_key): A new instance of the Groq client is created, authenticated using
the loaded API key.

4. Prepare a prompt:

 prompt = "What is the capital of France?": You define the user's question as a simple string, intended to be sent to the language model.

5. Call the language model:

- client.chat.completions.create(...): This sends a chat-style API call to the Groq server:
 - model="compound-beta" specifies the model to use.
 - messages=[{"role": "user", "content": prompt}] creates a conversation history containing only one user message: your question.
 - max_tokens=2048 defines the maximum length of the model's reply (up to 2048 tokens).
 - stop=None means no special stopping sequence is set; the model will stop when it reaches the
 end or the token limit.

6. Print the response:

print(completion.choices[0].message.content): After getting the model's reply, you access the
first choice's content and print it to the console.

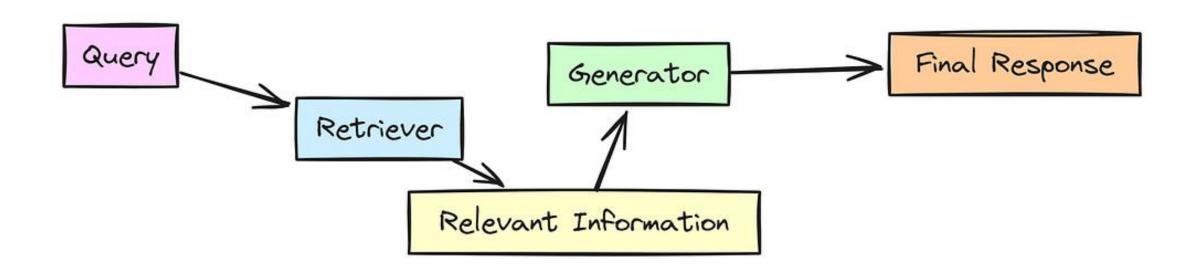

Retrieval Augmented Generation (RAG)

In this process:

- The **Query** is the user input.
- The **Retriever** searches the knowledge base and brings back relevant documents.
- The **Generator** combines the retrieved information and generates the final response.
